REC_Python_Week 4_MCQ

Attempt : 1
Total Mark : 15
Marks Obtained : 13

Section 1 : MCQ

1. What will be the output of the following code?

```
value = 42
result = abs(value) + len(str(value))
print(result)
```

Answer

44

Status : Correct ***Marks : 1/1***

2. What is the main advantage of using lambda functions in Python?

Answer

They allow you to write shorter code than regular functions

Status : Correct ***Marks : 1/1***

3. What will be the output of the following Python code?

```
multiply = lambda x, y: x * y
print(multiply(2, 'Hello'))
```

Answer

HelloHello

Status : Correct ***Marks : 1/1***

4. Which of the following functions can take a lambda function as a parameter in Python?

Answer

 max()

Status : Wrong ***Marks : 0/1***

5. What is the output of the following code snippet?

```
def my_function(x):
    x += 5
    return x

a = 10
result = my_function(a)
print(a, result)
```

Answer

10 15

Status : Correct ***Marks : 1/1***

6. What is the output of the following code?

```
x=12
def f1(a,b=x):
 print(a,b)
x=15
f1(4)
```

Answer

4 12

Status : Correct ***Marks : 1/1***

7. What keyword is used to define a lambda function in Python?

Answer

lambda

Status : Correct ***Marks : 1/1***

8. What will be the output of the following code?

```
num1 = 10
num2 = -10
result = abs(num1) + abs(num2)
print(result)
```

Answer

20

Status : Correct ***Marks : 1/1***

9. What will be the output of the following Python code?

```
def absolute_value(x):
    if x < 0:
        return -x
    return x

result = absolute_value(-9)
```

print(result, absolute_value(5))

Answer

9 5

Status : Correct ***Marks : 1/1***

10. How is a lambda function different from a regular named function in Python?

Answer

A lambda function can only take one argument, while a regular function can take multiple arguments

Status : Wrong ***Marks : 0/1***

11. What will be the output of the following code?

```
num = -5
result = abs(num)
print(result)
```

Answer

5

Status : Correct ***Marks : 1/1***

12. What is the output of the code shown?

```
def f1():
 global x
 x+=1
 print(x)
x=12
print("x")
```

Answer

x

Status : Correct ***Marks : 1/1***

13. What will be the output of the following Python code?

```
def display(b, n):
    while n > 0:
        print(b,end="")
        n=n-1
display('z',3)
```

Answer

zzz

Status : Correct ***Marks : 1/1***

14. What will be the output of the following code?

```
def display(*args):
    for arg in args:
        print(arg)

display(10, 20, 30)
```

Answer

102030

Status : Correct ***Marks : 1/1***

15. What will be the output of the following Python code?

```
def is_even(number):
    if number % 2 == 0:
        return True

result = is_even(6)
print(result)
```

Answer

True

Status : Correct ***Marks : 1/1***

REC_Python_Week 4_COD_Updated

Attempt : 1
Total Mark : 50
Marks Obtained : 50

Section 1 : Coding

1. Problem Statement

Imagine you are building a messaging application, and you want to know the length of the messages sent by the users. You need to create a program that calculates the length of a message using the built-in function len().

Input Format

The input consists of a string representing the message.

Output Format

The output prints an integer representing the length of the entered message.

Refer to the sample output for formatting specifications.

Sample Test Case

Input: hello!!

Output: 7

Answer

```
message = input()
length = len(message)
print(length)
```

Status : Correct ***Marks : 10/10***

2. Problem Statement

Sara is developing a text-processing tool that checks if a given string starts with a specific character or substring. She needs to implement a function that accepts a string and a character (or substring), and returns True if the string starts with the provided character/substring, or False otherwise.

Write a program that uses a lambda function to help Sara perform this check.

Input Format

The first line contains a string `str` representing the main string to be checked.

The second line contains a string `n`, which is the character or substring to check if the main string starts with it.

Output Format

The first line of output prints "True" if the string starts with the given character/ substring, otherwise prints "False".

Refer to the sample for the formatting specifications.

Sample Test Case

Input: Examly
e
Output: False

Answer

```
# You are using Python
# Read input
main_string = input().strip()
substring = input().strip()

# Lambda function to check the start of the string
starts_with = lambda s, sub: s.startswith(sub)

# Output the result
print(starts_with(main_string, substring))
```

Status : Correct ***Marks : 10/10***

3. Problem Statement

Sneha is building a more advanced exponential calculator. She wants to implement a program that does the following:

Calculates the result of raising a given base to a specific exponent using Python's built-in pow() function.Displays all intermediate powers from base¹ to base^exponent as a list.Calculates and displays the sum of these intermediate powers.

Help her build this program to automate her calculations.

Input Format

The input consists of line-separated two integer values representing base and exponent.

Output Format

The first line of the output prints the calculated result of raising the base to the exponent.

The second line prints a list of all powers from base^1 to base^exponent.

The third line prints the sum of all these powers.

Refer to the sample output for formatting specifications.

Sample Test Case

Input: 2
3
Output: 8
[2, 4, 8]
14

Answer

```
base = int(input())
exponent = int(input())
result = pow(base, exponent)
intermediate_powers = [pow(base, i) for i in range(1, exponent + 1)]
sum_of_powers = sum(intermediate_powers)
print(result)
print(intermediate_powers)
print(sum_of_powers)
```

Status : Correct ***Marks : 10/10***

4. Problem Statement

Implement a program that needs to identify Armstrong numbers. Armstrong numbers are special numbers that are equal to the sum of their digits, each raised to the power of the number of digits in the number.

Write a function is_armstrong_number(number) that checks if a given number is an Armstrong number or not.

Function Signature: armstrong_number(number)

Input Format

The first line of the input consists of a single integer, n, representing the number

to be checked.

Output Format

The output should consist of a single line that displays a message indicating whether the input number is an Armstrong number or not.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 153
Output: 153 is an Armstrong number.

Answer

```
def is_armstrong_number(number: int) -> None:
    num_str = str(number)
    num_digits = len(num_str)
    sum_of_powers = sum(int(digit) ** num_digits for digit in num_str)
    if sum_of_powers == number:
        print(f"{number} is an Armstrong number.")
    else:
        print(f"{number} is not an Armstrong number.")

n = int(input())
is_armstrong_number(n)
```

Status : Correct ***Marks : 10/10***

5. Problem Statement

Imagine you are developing a text analysis tool for a cybersecurity company. Your task is to create a function that analyzes input strings to categorize and count the characters into four categories: uppercase letters, lowercase letters, digits, and special characters. The company needs this tool to process log files and identify potential security threats.

Function Signature: analyze_string(input_string)

Input Format

The input consists of a single string (without space), which may include uppercase letters, lowercase letters, digits, and special characters.

Output Format

The first line contains an integer representing the count of uppercase letters in the format "Uppercase letters: [count]".

The second line contains an integer representing the count of lowercase letters in the format "Lowercase letters: [count]".

The third line contains an integer representing the count of digits in the format "Digits: [count]".

The fourth line contains an integer representing the count of special characters in the format "Special characters: [count]".

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: Hello123

Output: Uppercase letters: 1
Lowercase letters: 4
Digits: 3
Special characters: 0

Answer

```
def analyze_string(input_string):
    uppercase_count = 0
    lowercase_count = 0
    digit_count = 0
    special_count = 0
    for char in input_string:
        if char.isupper():
            uppercase_count += 1
        elif char.islower():
            lowercase_count += 1
```

```
        elif char.isdigit():
            digit_count += 1
        else:
            special_count += 1
    return uppercase_count,lowercase_count,digit_count,special_count

input_string = input()
uppercase_count, lowercase_count, digit_count, special_count =
analyze_string(input_string)

print("Uppercase letters:", uppercase_count)
print("Lowercase letters:", lowercase_count)
print("Digits:", digit_count)
print("Special characters:", special_count)
```

1. Problem Statement

Alice works at a digital marketing company, where she analyzes large datasets. One day, she's tasked with processing customer ID numbers, which are long numeric sequences.

To simplify her task, Alice needs to calculate the digital root of each ID. The digital root is obtained by repeatedly summing the digits of a number until a single digit remains.

Help Alice write a program that reads a customer ID number, calculates its digital root, and prints the result using a loop-based approach.

For example, the sum of the digits of 98675 is 9 + 8 + 6 + 7 + 5 = 35, then 3 + 5 = 8, which is the digital root.

Function prototype: def digital_root(num)

Input Format

The input consists of an integer num.

Output Format

The output prints an integer representing the sum of digits for a given number until a single digit is obtained.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 451110

Output: 3

Answer

```
num = int(input())

def digital_root(num):
    while num > 9:
        total = 0
        while num > 0:
            total += num % 10
            num //= 10
        num = total
    print(num)

print(digital_root(num))
```

Status : Wrong ***Marks : 0/10***

2. Problem Statement

Create a Python program to monitor temperatures in a greenhouse using two sensors. Calculate and display the absolute temperature difference between the two sensor readings to ensure proper temperature control.

Note: Use the abs() built-in function.

Input Format

The first line consists of a floating-point number, representing the temperature reading from Sensor 1.

The second line consists of a floating-point number, representing the temperature reading from Sensor 2.

Output Format

The output displays the absolute temperature difference between Sensor 1 and Sensor 2, rounded to two decimal places.

Refer to the sample output for the exact format.

Sample Test Case

Input: 33.2
26.7
Output: Temperature difference: 6.50 °C

Answer

```
# You are using Python
# Read temperature readings from both sensors
sensor1 = float(input())
sensor2 = float(input())

difference = abs(sensor1 - sensor2)

# Display the result rounded to two decimal places
print(f"Temperature difference: {difference:.2f} °C")
```

Status : Correct ***Marks : 10/10***

3. Problem Statement

Hussain wants to create a program to calculate a person's BMI (Body Mass Index) based on their weight in kilograms and height in meters. The BMI is a measure of a person's body fat relative to their height.

Your program should take user input for weight and height, calculate the BMI, and display the result.

Function Signature: calculate_bmi(weight, height)

Formula: BMI = Weight/(Height)2

Input Format

The first line of input consists of a positive floating-point number, the person's weight in kilograms.

The second line of input consists of a positive floating-point number, the person's height in meters.

Output Format

The output displays "Your BMI is: [BM] followed by a float value representing the calculated BMI, rounded off two decimal points.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 70.0
1.75

Output: Your BMI is: 22.86

Answer

```
weight = float(input())
height = float(input())

def calculate_bmi(weight, height):
    bmi = weight / (height ** 2)
    print(f"Your BMI is: {bmi:.2f}")
```

calculate_bmi(weight, height)

Status : Correct ***Marks : 10/10***

4. Problem Statement

Ravi is working on analyzing a set of integers to determine how many of them are divisible by 3 and how many are divisible by 5. He decides to use lambda functions to filter and count the numbers based on their divisibility.

Write a program that takes a list of integers, calculates how many numbers are divisible by 3, and how many are divisible by 5, and then prints the results.

Additionally, the program should calculate the total sum of all numbers divisible by 3 and divisible by 5 separately.

Input Format

The first line contains an integer n, representing the number of integers in the list.

The second line contains n space-separated integers.

Output Format

The first line should print the count of numbers divisible by 3.

The second line should print the count of numbers divisible by 5.

The third line should print the sum of numbers divisible by 3.

The fourth line should print the sum of numbers divisible by 5.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 6
3 5 6 10 15 20
Output: 3
4
24
50

Answer

```
# You are using Python
# Read input values
n = int(input())
numbers = list(map(int, input().split()))

div_by_3 = list(filter(lambda x: x % 3 == 0, numbers))
div_by_5 = list(filter(lambda x: x % 5 == 0, numbers))

# Output the required results
print(len(div_by_3))
print(len(div_by_5))
print(sum(div_by_3))
print(sum(div_by_5))
```

Status : Correct ***Marks : 10/10***

5. Problem Statement

Ella is designing a messaging application that needs to handle long text messages efficiently. To optimize storage and transmission, she plans to implement a text compression feature that replaces consecutive repeated characters with the character followed by its count, while leaving non-repeated characters unchanged.

Help Ella create a recursive function to achieve this compression without altering the original message's meaning.

Function Specification: def compress_string(*args)

Input Format

The input consists of a single line containing the string to be compressed.

Output Format

The output consists of a single line containing the compressed string.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: aaaBBBccc

Output: a3B3c3

Answer

```
# You are using Python
def compress_string(s):
    if not s:
        return ""

    # Count consecutive occurrences of the first character
    count = 1
    while count < len(s) and s[count] == s[0]:
        count += 1

    # Form compressed part
    compressed_part = s[0] + (str(count) if count > 1 else "")

    # Recursive call on the rest of the string after the counted characters
    return compressed_part + compress_string(s[count:])

# Read input
s = input()

# Print the compressed string
print(compress_string(s))
```

Status : Correct ***Marks : 10/10***

6. Problem Statement

Sophia is developing a feature for her online banking application that calculates the total sum of digits in customers' account numbers. This sum is used to generate unique verification codes for secure transactions. She needs a program that takes an account number as input and outputs the sum of its digits.

Help Sophia to complete her task.

Function Specification: def sum_digits(num)

Input Format

The input consists of an integer, representing the customer's account number.

Output Format

The output prints an integer representing the sum of the digits of the account number.

Refer to the sample output for formatting specifications.

Sample Test Case

Input: 123245
Output: 17

Answer

```
num = int(input())

def sum_digits(num):
    total = 0
    while num > 0:
        total += num % 10
        num //= 10
    print(total)

sum = sum_digits(num)
print(sum)
```

1. Problem Statement

Arjun is working on a mathematical tool to manipulate lists of numbers. He needs a program that reads a list of integers and generates two lists: one containing the squares of the input numbers, and another containing the cubes. Arjun wants to use lambda functions for both tasks.

Write a program that computes the square and cube of each number in the input list using lambda functions.

Input Format

The input consists of a single line of space-separated integers representing the list of input numbers.

Output Format

The first line contains a list of the squared values of the input numbers.

The second line contains a list of the cubed values of the input numbers.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 1 2 3
Output: [1, 4, 9]
[1, 8, 27]

Answer

```
# You are using Python
# Read input
numbers = list(map(int, input().split()))

squares = list(map(lambda x: x ** 2, numbers))
cubes = list(map(lambda x: x ** 3, numbers))

# Print the results
print(squares)
print(cubes)
```

Status : Correct ***Marks : 10/10***

2. Problem Statement

Implement a program for a retail store that needs to find the highest even price in a list of product prices. Your goal is to efficiently determine the maximum even price from a series of product prices. Utilize the max() inbuilt function in the program.

For example, if the prices are 10 15 24 8 37 16, the even prices are 10 24 8 16. So, the maximum even price is 24.

Input Format

The input consists of a series of product prices separated by a space.

The prices should be entered as a space-separated string of numbers.

Output Format

If there are even prices in the input, the output prints "The maximum even price is: " followed by the maximum even price.

If there are no even prices in the input, the output prints "No even prices were found".

Refer to the sample output for formatting specifications.

Sample Test Case

Input: 10 15 24 8 37 16

Output: The maximum even price is: 24

Answer

```
# You are using Python
# Read input
prices = list(map(int, input().split()))

# Filter even prices
even_prices = list(filter(lambda x: x % 2 == 0, prices))

# Check and output result
if even_prices:
    print("The maximum even price is:", max(even_prices))
else:
    print("No even prices were found")
```

Status : Correct ***Marks : 10/10***

3. Problem Statement

Develop a text analysis tool that needs to count the occurrences of a specific substring within a given text string.

Write a function count_substrings(text, substring) that takes two inputs: the text string and the substring to be counted. The function should count how many times the substring appears in the text string and return the count.

Function Signature: count_substrings(text, substring)

Input Format

The first line of the input consists of a string representing the text.

The second line consists of a string representing the substring.

Output Format

The output should display a single line of output containing the count of occurrences of the substring in the text string.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: programming is fun and programming is cool
programming
Output: The substring 'programming' appears 2 times in the text.

Answer

```
# You are using Python
def count_substrings(text, substring):
    count = text.count(substring)
    print(f"The substring '{substring}' appears {count} times in the text.")

# Read input
text = input()
substring = input()

# Call the function
count_substrings(text, substring)
```

Status : Correct ***Marks : 10/10***

4. Problem Statement

Meena is analyzing a list of integers and needs to count how many numbers in the list are even and how many are odd. She decides to use lambda functions to filter the even and odd numbers from the list.

Write a program that takes a list of integers, counts the number of even and odd numbers using lambda functions, and prints the results.

Input Format

The first line contains an integer n, representing the number of integers in the list.

The second line contains n space-separated integers.

Output Format

The first line of output prints an integer representing the count of even numbers.

The second line of output prints an integer representing the count of odd numbers.

Refer to the sample output for the formatting specifications.

Sample Test Case

Input: 7
12 34 56 78 98 65 23
Output: 5
2

Answer

```
# You are using Python
# Read input
n = int(input())
numbers = list(map(int, input().split()))

even_numbers = list(filter(lambda x: x % 2 == 0, numbers))
```

```
odd_numbers = list(filter(lambda x: x % 2 != 0, numbers))

# Print counts
print(len(even_numbers))
print(len(odd_numbers))
```

Status : Correct ***Marks : 10/10***
